Organic compounds may be classified in a variety of ways. One major distinction is between natural and synthetic compounds. Organic compounds can also be classified or subdivided by the presence of heteroatoms, e.g., organometallic compounds, which feature bonds between carbon and a metal, and organophosphorus compounds, which feature bonds between carbon and a phosphorus.

Relationships between molecular structure and reactivity using modern synthetic methods and advanced instrumentation. A materials fee is required. A natural product is a chemical compound or substance produced by a living organism—that is, found in nature. In the broadest sense, natural products include any substance produced by life. Natural products can also be prepared by chemical synthesis (both semisynthesis and total synthesis) and have played a central role in the development of the field of organic chemistry by providing. The 12th edition of organic chemistry continues solomons, fahy Snyder's tradition of excellence in teaching and preparing students for success in the organic classroom and beyond. A central theme of the authors approach to organic chemistry is to emphasize the relationship between structure and reactivity.

To accomplish this, the content is organized in a way that combines the most useful. Both chemical and physical, synthesis and applications of organic compounds, which always contain carbon as one of the element. Carbonyl Reactivity - Chemistry
Aldehydes and ketones are organic compounds which incorporate a carbonyl functional group, C=O. The carbon atom of this group has two remaining bonds that may be occupied by hydrogen or alkyl or aryl substituents. If at least one of these substituents is hydrogen, the compound is an aldehyde. If neither is hydrogen, the compound is a ketone.
